Is there Life on Mars?

Observations from Earth

- 5 The planet Mars appears as a red star-like object to the unaided eye. Its reddish colour encouraged the Romans to name the planet after their god of war and, since then, Mars has caught the imagination of astronomers and writers alike.**
- 10 Mars does not take a simple path through the skies that the ancient observers could easily explain using their model of an Earth-centred Universe with the Sun, Moon,**
- 15 planets and stars revolving around a stationary Earth. It took the genius of Johannes Kepler in the early decades of the seventeenth century to provide a simple explanation for**
- 20 Mars's reversals of direction in its journey through the constellations. Kepler reasoned that the planets, including Earth, travel around the Sun in ellipses and that the square**
- 25 of the orbital period of a planet is**

proportional to the cube of its mean distance from the Sun. Kepler's laws, an explanation for the puzzling behaviour of Mars, gave a new perspective on the Universe which Isaac Newton embraced in his theory of universal gravitation published in 1687.

Visual observations of the planets improved as telescopic astronomy developed, but some observers recorded details that have since proved to be illusions. In 1877, the Italian Giovanni Schiaparelli used favourable observing conditions to draw a map of Mars. He observed what he called *canali*, translated as canals, on the surface of Mars. This apparent observation was interpreted as evidence of liquid water on the planet.

Some other observers reported similar features. The American astronomer Percival Lowell made detailed drawings and believed that canals were made by intelligent

beings in an attempt to transport water from the poles of the planet to the barren equatorial regions. Many
55 astronomers were sceptical about Lowell's claims because of the limited resolution of the telescopes of the time but his ideas caught the popular imagination. For example, H.G. Wells
60 took Lowell's idea of a dying Mars and imagined its inhabitants attempting to colonise the Earth in his 1897 novel 'The War of the Worlds'.

A closer look

65 In 1971, Mariner 9 became the first space probe to orbit Mars and it succeeded in sending images back to Earth of a barren landscape that showed signs of water flow in
70 the distant past but no evidence of liquid water on the surface. However, Mariner revealed that Mars has a dramatic geological past that produced, among many other
75 features, a huge system of canyons, the 'Valles Marineris', which cuts across 4000 km of the surface of the

planet, reaching depths of 7 km. This
can be seen in the right-hand image
80 of Fig. 1 opposite. Mariner 9 also
discovered the largest volcano in the
Solar System, Olympus Mons, with a
crater 80 km wide and standing about
27 km above the average surface
85 height.

FIG. 1

**'Valles
Marineris'**

**Map by Lowell's team (left) and an image from the Viking 1
orbiter (1976)**

90 Mariner was followed by the Viking 1
lander, which touched down on the
surface of Mars in 1976. One of the
purposes of the mission was to
search for evidence for simple life
95 on the planet. Viking found no such
evidence and data from more recent
landers suggests that Mars is unlikely
to have ever supported even the
simplest life form.

Visitors from Mars

100 The Earth is frequently struck by
small fragments of rocky material.
Some of these are known to have
originated on Mars. It is thought that
a collision between the planet and
105 an asteroid or comet could give the
fragments sufficient energy to escape
Mars. Some scientists think that there
is fossil evidence of possible simple
life forms in samples of the Martian
110 meteorites, but this is disputed.

Visitors to Mars

Recent years have seen a growing interest in human missions to Mars. Perhaps, rather than the terrifying machines of ‘The War of the Worlds’ colonising Earth from a failing planet, humans will colonise Mars from an overcrowded, resource-hungry world. It is known that there is sufficient water-ice on and under the planet for a colony to be set up and Mars has many minerals vital to maintaining such a venture. However, there are numerous practical problems to overcome because Mars is a very different world from Earth. Colonising Mars is a technical and scientific challenge that dwarfs any other attempted by humankind.

- 130 Mars data: gravitational field strength at surface = 3.7 N kg^{-1}**
- mass = $6.4 \times 10^{23} \text{ kg}$**
- 135 average surface temperature = 210 K**
- atmospheric pressure at surface = 0.6 kPa**
- orbital radius = $2.3 \times 10^{11} \text{ m}$**
- 140 Atmosphere: 95% carbon dioxide, 3% nitrogen, remaining fraction composed of argon and trace amounts of other gases**
- 145 The small size of Mars means that it has kept little of any atmosphere it may have once had. The Earth's atmosphere is protected from a large proportion of cosmic rays and other**
- 150 charged particles by its magnetic field, producing a magnetic barrier**

around the Earth known as the magnetosphere. Although Mars had a magnetic field in earlier times, it
155 now has no such field and a greater proportion of charged particles from the Sun reach the surface of the planet, giving a higher intensity of radiation and increasing the rate of
160 loss of atmosphere. The low pressure on the surface of Mars means that humans will be required to wear pressure suits when outside their pressurised cabins. The dangers from
165 radiation will limit time spent outside living quarters, which will need to be carefully designed and located. Such buildings require materials and energy to construct. If the materials
170 are not transported from Earth, the early missions to the planet will need to seek the minerals required and set up production plants. Some energy will be available from sunlight, but
175 the inverse-square law shows that the available energy will be lower than that at Earth.

Terraforming Mars

180 An even more ambitious plan than setting up colonies on Mars and protecting the new Martians from their hostile environment is to change the environment to suit humans, a process known as ‘terraforming’.

185 Two major challenges faced are: (a) to increase the amount of carbon dioxide in the atmosphere to produce global warming and (b) to create a magnetosphere to reduce the

190 intensity of radiation at the surface and slow down the loss of the new gases pumped into the atmosphere. Mars has sufficient carbon dioxide as dry ice in its polar regions to

195 significantly increase the atmospheric pressure. One suggestion is to use orbiting mirrors to focus sunlight on the polar regions to release

200 gaseous carbon dioxide. If sufficient carbon dioxide is introduced into the atmosphere, liquid water will remain on the surface rather than rapidly evaporating.

**205 Pumping more gas into the
atmosphere will not be worthwhile
if cosmic rays are allowed to strip
the atmosphere away. It has been
suggested that a magnetic shield
210 might be placed between the Sun and
Mars to direct cosmic rays away from
the planet in a similar fashion to the
magnetosphere around Earth.**

**215 The idea is that the shield is placed
at the 'L1' point between Mars and
the Sun (Fig. 2 over the page). At this
position, the shield will orbit the Sun
at the same rate as Mars so the shield,
Mars and the Sun will remain in line.
220 The gravitational pull of Mars reduces
the centripetally acting gravitational
force on the shield from the Sun as
the force due to Mars acts in the
opposite direction to that of the Sun.
225 The values of the forces due to Mars
and the Sun give a net force on the
shield that is precisely that required
to orbit the Sun at the same rate as
Mars, even though it is nearer the
Sun.**

FIG. 2

230 Many scientists and engineers are
working on developing technologies
and systems to allow humans to
reach Mars, and possibly stay on
the surface of the planet. NASA
235 has recently stated that it hopes to
have humans on the surface in the
2030s and Russia has made a similar
statement of intent. Private companies
are also investigating missions to
240 the red planet. Perhaps the answer to
David Bowie's question 'Is there life
on Mars?' is: not at the moment, but
in a few decades' time, who knows?
